AS MOST readers will know, pasture dieback has caused significant productivity losses over recent years. Rain has improved pasture conditions, but dieback is still present where seen previously and in new locations. Due to its impact, Department of Agriculture and Fisheries has a program to help graziers. Characterisation of the condition across the state, is important. This has been valuable to determine the impacts of dieback, map its location and to better understand factors that might predispose pastures to attack. This work indicates that millions of hectares may be affected, causing significant economic impacts.

Diagnostic research into the causes of dieback continues. The scientific team are investigating whether fungi, bacteria, viruses, insects or a combination of these, are causes. At this stage it is unlikely dieback is caused by fungal organisms. A range of fungi have been detected in the field but have not caused plant death in multiple investigations. DAF is investigating the potential involvement of viruses, bacteria or phytoplasmas.

The rule pasture mealybug may have in dieback is a focus of DAF research. For mealybug to be the direct cause of dieback, infested plants must express the full cycle of symptoms - leaf yellowing and or reddening, stunted growth, early senescence and death. Several grass species infested with mealybugs in controlled glasshouse experiments (in the absence of other pathogenic organisms) showed dieback-like symptoms but failed to die. This indicates mealybugs are not the direct or sole cause of dieback.

Field trials investigating management options to restore productivity continue at Brian Pastures Research Station, Gayndah and have demonstrated that sowing legumes (annual or perennial) into affected paddocks can restore forage availability. Annual forages such as sorghum or oats have not been affected by dieback. Results indicate variation in grass species’ tolerance to dieback, however, it is uncertain if any are resistant.

In February 2020, a new field site was planted near Kalbar, southern Queensland with 26 different grass species.

The DAF pasture dieback project will continue to seek answers to the many unanswered questions. We have close working relationships with organisations undertaking complementary research, including MLA (and partners), University of Queensland, Central Queensland University, and Fitzroy Basin Association.

Keep an eye on calves

The Calf Watch project aims to develop a system to remotely monitor calving and study calf loss in northern Australia.

Calf loss is a major source of lost income for beef producers in northern Australia and reducing calf loss has the potential to improve weaning rates and profitability. Previously it has been difficult to investigate the causes of calf loss as calving females and calf carcasses are hard to find in large paddocks, therefore few autopsies are able to be conducted to determine the cause of calf deaths.

A system to remotely monitor calving in extensive areas would provide great benefits for research on calf loss in northern Australia. The Calf Watch project aims to meet this need.

The Calf Watch project is being conducted at Manbullo Station near Katherine (NT) in a 2215 hectare uncleared paddock of native pasture. Four gateways with external antennas mounted on 12 metre high towers give adequate coverage of the paddock.

In August 2019, 189 pregnant cows were fitted with birthing sensors and GPS tracking collars, and another 10 cows were fitted with GPS collars only.

It was very dry and hot (mean maximum temperatures of around 40 degrees) during most of the October and December calving period, and the cows congregated around the single water point for most of the day before leaving in the late afternoon to graze.

This allowed daily visual checks to be made. If calving cows could not be located using GPS data, observations were recorded when they came for water in the days after calving. Alerts were successfully received from 85 per cent of birth sensors. However, some GPS collar locations or did not come to the water point during the day, and some GPS collar locations or did not come to the water point during the day.

A calving alert is then sent and is immediately viewable on a website. The cows were fitted with GPS tracking collars that record location every 15 minutes, enabling cows to be located at the time of an expulsion alert and the location data is viewable in real time on a website.

A system to remotely monitor calving would be a game changer for research into calf loss in northern Australia.
Consider early weaning

Look at weaning your calves early as a dry season management option to save costs and give your herd a boost.

Early weaning is a powerful and cost-effective dry season management option for your cows. Early weaning refers to calves three to four months of age and roughly 100 kilograms. However, calves can be weaned as light as 60kg in extreme drought conditions where cow health is at risk, provided you feed calves a high protein (18 per cent) diet.

Early weaning is the most effective management tool available to help cows hold or improve body condition and fertility. Feeding the lactating cow-calf unit does not benefit cow condition as the nutrition is transferred into milk for the calf.

It is more efficient and cost-effective to supplement feed cows and calves separately, rather than feeding the calf through the cow. Once a calf is weaned, the cow’s feed and water requirements decrease by up to 40pc and 60pc respectively. Weaning the calf and therefore removing the need for cows to lactate in the early dry season, is equivalent to giving them up to 2kg of grain or 3kg of fortified molasses every day.

When to wean

Cow body condition is the key criterion for deciding when to wean. Ideally, aim to have calves around three months of age or 100kg as by this age their protein requirements aren’t as high and they are used to grazing. Other key factors to consider are the severity and length of dry conditions, time of year relative to expected rainfall, current pasture availability and the price of supplements.

Feeding rates

Calves’ dietary requirements change with different stages of growth and you need to feed them accordingly.

The feeding rates below are a guide to maintain calf weight or get slight weight gains. Calf performance is the best measure of how much supplement they need and you should adjust their intakes accordingly.

**Feeding rates** for calves two to four months old (60-120kg)

Feed unlimited pasture if available or 0.25 to 0.5kg per head per day of grassy lucerne hay, good quality grass or forage hay. Beware of scours, particularly on lucerne hay. In addition, feed one of the following supplements:

- 0.5 to 1kg head/day grain mix (three parts crushed grain, one part protein meal, 2pc limestone)
- 0.25 to 0.5kg head/day protein meal

**Feeding rates** for calves four to six months old (120-150kg)

Feed unlimited pasture or hay plus one of the following supplements:

- 1kg head/day grain mix
- 0.5kg head/day protein meal
- Calf pellets etc, as per manufacturer’s recommendations

**Feeding rates** for calves over 150kg

Feed unlimited pasture or hay plus one of the following supplements:

- 0.5kg head/day protein meal
- 1kg head/day of molasses plus 3pc urea and 8-10pc protein meal
- 0.5kg head/day whole cottonseed
- Draft calves accordingly to size and weight
- Draft calves that reach the threshold for higher weight into a separate group to reduce competition and possibly the cost of feeding.

It is important to reduce stress as much as possible. If practical, train calves to eat supplements before weaning and get them on solid feed as quickly as possible.

Avoid sudden changes in supplements because rumen bacteria need time to adjust. Ensure calves always have access to an adequate supply of fresh, clean water.

**Calf health**

Vaccinate all calves at weaning with 5 on 7-in-1 to protect against clostridial diseases such as pulpy kidney and tetanus. Young calves are very susceptible to parasites so treat all calves for internal and external parasites four to six weeks after weaning.

Use feeding racks for hay and troughs for meals, providing enough space to avoid contamination with dust and dung.

Minimise stress whenever possible, particularly when handling the calves and make sure they have adequate food, water and shelter.

Closely observe weaned calves for any signs of stress or illness such as scours.

In summary, for successful early weaning:

- Segregate calves according to age to reduce competition
- Start calves on a high-quality ration the day they are weaned to reduce stress
- Always vaccinate and monitor calves for disease.

When you are tailing early weaning for the first time, one option is to start with just a portion of your herd. Consider weaning just your first calf heifers early, as they are one of the most valuable mobs in terms of potential future breeding genetics. They can also be the most challenging group to get back in calf, particularly after an extended dry period.

The other priority mob for early weaning are your oldest breeders.

TRADITIONALLY, Merino wethers were seen as a sideline addition to wool growing enterprises, which are predominantly focused on ewes and lambs.

Today, wool and sheepmeat prices combined with improved exclusion fencing make wethers an attractive prospect in their own right. Extension officer with the Queensland Department of Agriculture and Fisheries, Jed Sommerfield, said benefits of purchasing and retaining wethers include income from a wool clip at least once a year and flexibility in dry times.

"They provide an easy back door option if the season turns dry. High wool and stable mutton prices offer flexibility to your business, providing an easy sell option and allowing you to reduce total grazing pressure and maintain ground cover. Ground which will have an improved response from your country when the rain returns," he said.

The lower maintenance aspect of a wether flock is also appealing, and an approach including multiple shearings before selling into the mutton market can provide a low input, high return investment. While currently an attractive prospect, the profitability of trading wethers is closely linked to wool returns. Wool prices have maintained strength in previous years, and continue to provide high yields, despite global economic headwinds in the form of coronavirus, Brexit and the US-China trade dispute," Mr Sommerfield said.

"At present, 20-micron wool is fetching roughly 1500 cents a kilogram clean. Add to this the high demand for sheepmeat, driven largely by a drought reduced flock, buying, shearing and selling wethers can be an attractive enterprise. With a lower constant plain of energy and nutritional requirements, wethers can be run on country which might be unproductive for ewes and lambs.

Traditionally wethers are shorn once every 12 months, shortening this period can boost cash flow. Producers are reminded to consider the market, increased shearing costs and labour availability associated with more frequent shearings, if unsure seek advice from your broker.

Several years of very challenging seasonal conditions have had a significant impact on Australian sheep numbers and wool production. While currently an attractive option for producers looking to restock, factors like purchase price, animal husbandry and shearing costs should be factored into any calculation.

"Adapting your enterprise to become drought resilient is essential to long-term sustainability and profitability," Mr Sommerfield said.

"Purchasing, shearing and selling Merino wethers can be easier to manage and provide high returns and business flexibility."

DEVELOP A DEEP UNDERSTANDING OF YOUR BUSINESS' GROSS MARGINS

WITH national flock numbers greatly reduced by prolonged drought, widespread recent rainfall has resulted in high demand and high prices for sheep. On top of this, data from the NSW Department of Primary Industries indicates standard sheep enterprise gross margins increased on average by about $6.56 in 2018, to roughly $50/DSE, or $500/hectare, at a stocking rate of 10 DSE/ha. While average stocking rates in western Queensland are slightly lower, sheep are still a very appealing option for producers looking to restock.

Extension officer with the Queensland Department of Agriculture and Fisheries, Jed Sommerfield, said producers considering purchasing sheep are encouraged to calculate achievable gross margins for their enterprise. "Current price and seasonal conditions, combined with the increased implementation of exclusion fencing across sheep production regions in western Queensland, means sheep are an attractive option for producers at the moment," Mr Sommerfield said.

"Despite this, it’s important people are thorough in their planning before deciding to buy. Factors like available feed and associated stocking rates, lambing percentages, growth rates, wool and sheepmeat prices all need to be considered."

"On top of this, costs like purchase price, animal husbandry and shearing costs should be factored into any calculation. To be accurate, gross margin calculations need to be specific to each individual property and business."

To assist you in calculating your gross margins, contact leadingsheep@daf.qld.gov.au for confidential help.

LEAP INTO SHEEP

Webinar launched for industry newcomers

A webinar series is aimed at getting into sheep can learn from Australia’s leading industry experts, via a new webinar series.
